

# Controlling behaviours and technology-facilitated abuse perpetrated by men receiving substance use treatment in England and Brazil: prevalence and risk factors

**Martha Canfield  
Polly Radcliffe, Ana Flavia D'Oliveira,  
Gail Gilchrist**

## Controlling behaviour in intimate relationships

- It is a highly prevalent form of non-physical violence and while it often co-occurs with physical and sexual violence in intimate relationships, there are different opinions as to whether it is always a constituent part of intimate partner violence (IPV) (Morgan & Bjorker, 2006).

# Controlling behaviour in intimate relationships

---

- Different typologies for IPV perpetrator based on the nature of the violence (Kelly & Johnson, 2008):
  - Intimate Terrorism (a pattern of emotionally abusive intimidation, coercion, and control)
  - Violent Resistance (to a violent, coercively controlling partner),
  - Situational Couple Violence (violence that does not have its basis in the dynamic of power and control)
- Behaviours that include control over a partner's access to resources, to freedom of movement, and decision making, negatively affect the victim and, it is argued can be equal to or more threatening than physical or sexual assault (DeKeseredy W, 2000; Logan et al, 2006)

# Technology-facilitated abuse (TFA)

- A wide variety of technology is now being used to abuse partners including email, text messaging, phone calls, social media and GPS tracking (Burke et al., 2011; Ringrose et al., 2012)

- 40%-73% of US college students have experienced such cyber abuse in dating relationships (Marganski & Melander, 2015; Wolford et al., 2016)
- In Australia, 78% female survivors of IPV reported receiving text messages (Woodlock, 2016)

- The increasingly widespread use of mobile technologies provides a means for perpetrators to easily and repeatedly control, harass, stalk and intimidate partners from a distance (Fraser et al., 2010)
- Research suggests that victims of stalking via technological means do not always perceive that they are experiencing abuse (Woodlock, 2016)

# IPV Perpetration

- Previous research has shown that rates for IPV perpetration are higher among men receiving treatment for substance use than for men in the general population (eg., Gilchrist et al., 2015; Smith et al., 2012)
- While alcohol and drug use are widely accepted risk factors for IPV there remains debate over the role of substance use (Stith et al, 2004)
- Societies that support stronger ideologies of male dominance have elevated rates of IPV. While the prevalence rates of controlling behaviour and physical and sexual IPV vary across cultures and countries, the association between these behaviours persists (Jewkes , 2007)
- Not clear how this varies across cultural settings and what role for example ‘machismo’ culture (a system of values and ideas that institutes, reinforces and legitimises men’s domination over women) may play.

# Current study

---

❖ Although there is growing recognition of controlling behaviours and TFA, the prevalence of these behaviours remains understudied, and has not been studied in groups at high risk of other IPV perpetration, such as men in treatment for substance use.

## Aims:

- To examine the **prevalence** of controlling behaviours and TFA by men receiving treatment for substance use in two distinct societies, England and Brazil.
- To describe the sociodemographic, psychological, and cultural **factors associated with** perpetrating controlling behaviour and TFA.
- To explore the **association between perpetrating and being a victim** of controlling behaviours and TFA with other forms of IPV victimisation and perpetration (emotional, physical, and sexual).

# Methods

---

## ***Design***

- A secondary analysis of two cross-sectional studies (England n= 223 and Brazil n=280)

## ***Measurements***

- socio-demographic characteristics, infidelity, IPV perpetration and victimisation, adverse childhood experiences (ACE), attitudes towards gender relations and roles, substance use, depressive symptoms, and anger expression.

## ***Sample***

- Aged 43 years (SD 10.6) on average
- 96.6% were heterosexual (96.8% Brazil, 96.4% England)
- The most commonly used drugs in the past 30 days were cocaine (Brazil), crack, heroin (England) and cannabis; 70.2% reported hazardous drinking (74.0% Brazil, 65.3% England).

# Results: Prevalence

---

## Controlling Behaviours

- Highly prevalent in both the Brazil (65%) and English (64.1%) samples

## Technology-facilitated abuse (TFA)

- Participants from England (32.7%) were almost twice as likely as participants from Brazil (20.4%) to report TFA (OR 1.90, 95%CI 1.27, 2.85).

**Participants who reported perpetrating controlling behaviours were almost seven times more likely to also have reported perpetrating TFA (OR 6.94, CI95% 3.7, 12.76).**

# Results: Prevalence

---

- Similar rates of perpetrating controlling behaviours between countries were reported but lower rates of perpetrating TFA were reported in Brazil compared to England, potentially due to lower access to such technologies in Brazil.
- In 2015, 76% of the UK adult population had access to the internet and 52% of people in treatment for substance use had smartphones compared to 56% of the Brazilian population having access to the internet and 28% having a smartphone.
- Our findings, therefore, highlight the role that technological advancements has on providing additional opportunities for perpetrators to control, stalk and abuse their partners more frequently and easily

# Results

---

- Participants in our study who were more supportive of gender equitable norms were less likely to report controlling behaviour.
- It is interesting that in spite of the higher support for gender equitable relations and less gender stereotyped attitudes towards gender roles in England compared to Brazil, the prevalence of perpetrating controlling behaviour was almost identical.
- The data from Brazil partially supports the concept that physical IPV may be used to maintain 'coercive control', while the data from England suggests that more subtle forms of IPV including TFA may also be used to enforce control in a cultural context where male domination and IPV is less socially accepted.

Multivariate analysis  
(excluding intimate partner violence victimisation)

Brazil

❖ **CONTROLLING BEHAVIOURS**

- Severe Physical IPV perpetration
- Number of adverse childhood experiences (ACE)

❖ **TECHNOLOGY-FACILITATED ABUSE (TFA)**

- Age

England

- Victim of controlling behaviour

### ❖ TFA

- Age
- Victim of TFA

England

### ❖ CONTROLLING BEHAVIOURS

- Emotional IPV victimisation
- Number of adverse childhood experiences (ACE)
- Victim of controlling behaviour
- Anger Expression Index

### ❖ TFA

- Age
- Victim of TFA

# Results

---

- Cultural differences.** It is possible that in cultures such as England where there is lower acceptability of severe physical IPV, controlling behaviour may substitute for physical IPV.
- ACE.** Studies suggest that experiencing ACE can have an impact on the threat-appraisal response system and result in hyper-reactivity to later stressors in life. Heightened reactivity to stress has been argued to be the potential link between childhood adversities, anger and IPV perpetration (eg., Welles et al, 2011; Iverson et al, 2014)
- Younger age.** the only factor associated with TFA, even when IPV victimisation was included in the model reflecting generational differences in technology use

# Recommendations

---

- Limited evidence to recommend risk assessment tools in predicting and measuring controlling behaviour, but TFA should be considered within any assessment of IPV.
- Urgent need for policy and legal responses to address TFA in the context of IPV.
- The fact that younger participants were more likely to perpetrate TFA, suggests that the negative use of technology in intimate relationships should be a focus of prevention strategies to reduce IPV perpetration.
- Risk factors for perpetrating controlling behaviours and TFA identified could offer ways of improving interventions aimed at preventing and reducing IPV among men receiving treatment for substance use.
